Manual assisted cognitive behaviour therapy is as effective as treatment as usual for deliberate self harm, but is more cost effective

is manual assisted cognitive behaviour therapy more effective and more cost effective than treatment as usual in people with recurrent episodes of deliberate self harm?

Methods

Design: Randomised controlled trial.
Allocation: Concealed.
Blinding: Unblinded.
Follow up period: 12 months.
Patients: 480 people, aged between 16 and 65 years, presenting with recurrent (at least 2 episodes) deliberate self harm. Exclusions: diagnosis of a psychotic or bipolar disorder; needing in-patient psychiatric treatment; primary diagnosis of substance dependence.
Intervention: Participants were randomised to manual assisted cognitive behaviour therapy (MACT; 239 people) or treatment as usual (TAU; 241 people). The MACT group received a booklet based on cognitive behavioural therapy (CBT) principles and were offered up to 7 sessions with a MACT trained therapist. The TAU group was offered the standard treatment available in each location, including: problem solving approaches (Nottingham); dynamic psychotherapy (South London); GP or voluntary group referral (West London and Edinburgh); or short term counselling (Glasgow). Members of the TAU group already receiving standard care were offered continuation of this care. Assessment interviews were carried out at 6 and 12 months. Incidences of self harm were self reported during a modified Linehan Parasuicide History Interview and verified using GP notes and A&E records. Economic data were collected at baseline, 6 and 12 months, using a modified Client Service Receipt Inventory. Data collected covered all service providing sectors, productivity losses, accommodation and living costs.
Outcomes: Efficacy: a repeat self harm episode within the following year. Cost: cost per patient over 12 months. Cost effectiveness: incremental cost effectiveness ratio (ICER) over 12 months.
Patient follow up: Efficacy analysis 84%; cost analysis 83%.

Main Results

Efficacy: at 12 months, the proportion of participants repeating deliberate self harm was not significantly different between groups (AR 39% with MACT v 46% with TAU; OR 0.78, 95% CI 0.53 to 1.14; analysis not by intention to treat). Cost: MACT was significantly cheaper than TAU over 6 months, but did not maintain significance over 12 months (6 month mean difference in cost per patient: –£897, 95% CI –£1747 to –£48; 12 month mean difference in cost per patient: –£838, 95% CI –£2142 to £466). Cost effectiveness: the ICER was –£120 per 1% reduction in the proportion of participants with a repeat self harm episode. The likelihood that MACT is more cost effective than TAU, based on cost effectiveness acceptability curves, is over 90%.

Conclusions

MACT is as effective as usual treatment in reducing recurrences of deliberate self harm, however, it is more cost effective.

Notes

Authors note that there were sociodemographic differences between participants included and those excluded from the economic analysis due to missing economic data. There was a centre bias among excluded participants, and they were younger and had cost less in the 6 months prior to baseline. This may affect generalisability of results.
Manual assisted cognitive behaviour therapy is as effective as treatment as usual for deliberate self harm, but is more cost effective
